Reflection Questions

1. Did your estimations reflect the actual effort?
Broadly yes — the Fibonacci scale forced realistic differentiation between simple validation rules (1-2 pts) and complex, uncertain work like third-party calendar sync (8 pts). Since this was a simulated sprint rather than actual development, "actual effort" couldn't be measured against real time spent, but the relative sizing across stories felt proportionate to their technical complexity and known unknowns.

2. Was your backlog well-prioritized?
Mostly. High-priority items (time-credit ledger, profile creation, booking flow, security) were correctly ranked above supporting features like search filters and reminders. One gap: calendar sync (PSE-15, 8 points) was tagged Medium priority despite being the highest-effort story — in hindsight it might deserve High priority given how much schedule risk it carries.

3. How did your simulated sprint align with your plan?
The sprint completed 3 of 5 planned stories (8 of 14 points, ~57%) within the simulation window, with 2 stories (PSE-10, PSE-13) left in To Do. This is a reasonably realistic reflection of a team that slightly over-committed for a first sprint — common in early iterations before velocity is established.

4. What insights did the burndown chart give about your team's capacity?
The burndown chart shows the remaining-work line dropping from 14 to 6 points by the end of the completion window, which sits below the guideline line — meaning the team

completed work faster than the linear pace would predict. This suggests the team had good capacity for a first sprint, though the two remaining stories (PSE-10 at 1 point, PSE-13 at 5 points) show that larger, more complex stories like calendar-dependent booking flows take longer to close out than smaller validation tasks. Future sprints could probably handle a similar 14-point load, but should sequence high-complexity items earlier rather than leaving the biggest story for last
